

## Object detection as supervised classification

Thurs April 13

Kristen Grauman  
UT Austin

---

---

---

---

---

---

---

### Last time

- Discovering visual patterns
  - Randomized hashing algorithms
  - Mining large-scale image collections

---

---

---

---

---

---

---

### Review questions: on your own

- What kind of input data is searchable with min-hash hashing?
- What kind of input data is searchable with LSH using random projections?
- For Visual “PageRank” what do weights between nodes (images) signify?

---

---

---

---

---

---

---

What does recognition involve?

Fei-Fei Li

---

---

---

---

---

---

---

---

Detection: are there people?

---

---

---

---

---

---

---

---

Activity: What are they doing?

---

---

---

---

---

---

---

---

Object categorization

---

---

---

---

---

---

---

---

Scene and context categorization

---

---

---

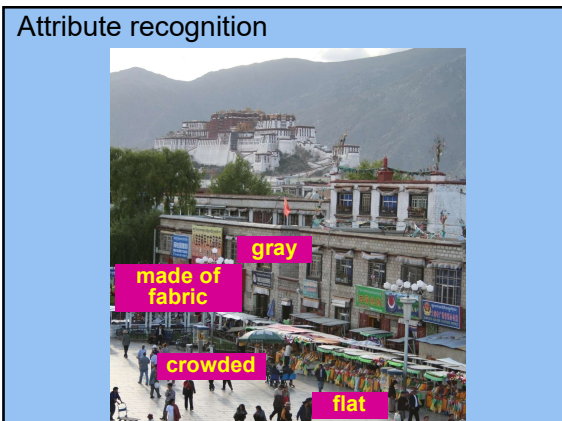

---

---

---

---

---

---

---

---

---

---

---

---

---

### Object Categorization

- Task Description
  - “Given a small number of training images of a category, recognize a-priori unknown instances of that category and assign the correct category label.”
- Which categories are feasible visually?

“Fido”   German shepherd   dog   animal   living being

K. Grauman, B. Leibe

Visual Object Recognition Tutorial

---

---

---

---

---

---

---

---

### Visual Object Categories

- Basic Level Categories in human categorization [Rosch 76, Lakoff 87]
  - The highest level at which category members have similar perceived shape
  - The highest level at which a single mental image reflects the entire category
  - The level at which human subjects are usually fastest at identifying category members
  - The first level named and understood by children
  - The highest level at which a person uses similar motor actions for interaction with category members

K. Grauman, B. Leibe

Visual Object Recognition Tutorial

---

---

---

---

---

---

---

---

### Visual Object Categories

- Basic-level categories in humans seem to be defined predominantly visually.
- There is evidence that humans (usually) start with basic-level categorization *before* doing identification.
  - ⇒ Basic-level categorization is easier and faster for humans than object identification!
  - How does this transfer to automatic classification algorithms?

K. Grauman, B. Leibe

---

---

---

---

---

---

---

---

How many object categories are there?

Source: Fei-Fei Li, Rob Fergus, Antonio Torralba. Biederman 1987

---

---

---

---

---

---

---

---

~10,000 to 30,000

---

---

---

---

---

---

---

---

Visual Object Recognition Tutorial

### Other Types of Categories

- Functional Categories
  - e.g. chairs = "something you can sit on"

K. Grauman, B. Leibe

---

---

---

---

---

---

---

---

### Why recognition?

- Recognition a fundamental part of perception
  - e.g., robots, autonomous agents
- Organize and give access to visual content
  - Connect to information
  - Detect trends and themes

---

---

---

---

---

---

---

---

### Autonomous agents able to detect objects

---

---

---

---

---

---

---

---

**Challenges: complexity**

- Millions of pixels in an image
- 30,000 human recognizable object categories
- 30+ degrees of freedom in the pose of articulated objects (humans)
- Billions of images online
- 82 years to watch all videos uploaded to YouTube per day!
- ...
- About half of the cerebral cortex in primates is devoted to processing visual information [Felleman and van Essen 1991]

Slide: Kristen Grauman

---

---

---

---

---

---

---

---

### Challenges: learning with minimal supervision

Less ← | | → More

Unlabeled, multiple objects

Classes labeled, some clutter

Cropped to object, parts and classes labeled

### Next

- Supervised classification
- Window-based generic object detection
  - basic pipeline
  - boosting classifiers
  - face detection as case study

---

---

---

---

---

---

---

---

### Supervised classification

- Given a collection of *labeled* examples, come up with a function that will predict the labels of new examples.

“four”

“nine”

Training examples

Novel input

- How good is some function we come up with to do the classification?
- Depends on
  - Mistakes made
  - Cost associated with the mistakes

---

---

---

---

---

---

---

---

### Supervised classification

- Given a collection of *labeled* examples, come up with a function that will predict the labels of new examples.
- Consider the two-class (binary) decision problem
  - $L(4 \rightarrow 9)$ : Loss of classifying a 4 as a 9
  - $L(9 \rightarrow 4)$ : Loss of classifying a 9 as a 4
- Risk** of a classifier  $s$  is expected loss:  

$$R(s) = \Pr(4 \rightarrow 9 \mid \text{using } s)L(4 \rightarrow 9) + \Pr(9 \rightarrow 4 \mid \text{using } s)L(9 \rightarrow 4)$$
- We want to choose a classifier so as to minimize this total risk

---

---

---

---

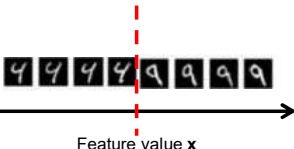

---

---

---

---

### Supervised classification

Feature value  $x$

Optimal classifier will minimize total risk.

At decision boundary, either choice of label yields same expected loss.

If we choose class "four" at boundary, expected loss is:  
 $= P(\text{class is } 9 \mid x) L(9 \rightarrow 4) + P(\text{class is } 4 \mid x) L(4 \rightarrow 4)$

If we choose class "nine" at boundary, expected loss is:  
 $= P(\text{class is } 4 \mid x) L(4 \rightarrow 9)$

---

---

---

---

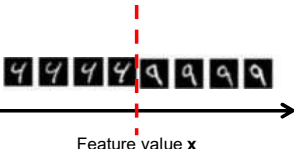

---

---

---

---

### Supervised classification

Feature value  $x$

Optimal classifier will minimize total risk.

At decision boundary, either choice of label yields same expected loss.

So, best decision boundary is at point  $x$  where  

$$P(\text{class is } 9 \mid x) L(9 \rightarrow 4) = P(\text{class is } 4 \mid x) L(4 \rightarrow 9)$$

To classify a new point, choose class with lowest expected loss; i.e., choose "four" if  

$$P(4 \mid x)L(4 \rightarrow 9) > P(9 \mid x)L(9 \rightarrow 4)$$

---

---

---

---

---

---

---

---

### Supervised classification

Optimal classifier will minimize total risk.

At decision boundary, either choice of label yields same expected loss.

So, best decision boundary is at point  $x$  where

$$P(\text{class is } 9 | x) L(9 \rightarrow 4) = P(\text{class is } 4 | x) L(4 \rightarrow 9)$$

To classify a new point, choose class with lowest expected loss: i.e., choose "four" if

$$P(4 | x) L(4 \rightarrow 9) < P(9 | x) L(9 \rightarrow 4)$$

---

---

---

---

---

---

---

---

### Example: learning skin colors

- We can represent a class-conditional density using a histogram (a "non-parametric" distribution)

Slide: Kristen Grauman

---

---

---

---

---

---

---

---

### Example: learning skin colors

- We can represent a class-conditional density using a histogram (a "non-parametric" distribution)

Now we get a new image, and want to label each pixel as skin or non-skin.  
What's the probability we care about to do skin detection?

Slide: Kristen Grauman

---

---

---

---

---

---

---

---

### Bayes rule

$$P(\text{skin} | x) = \frac{\overbrace{P(x | \text{skin})}^{\text{likelihood}} \overbrace{P(\text{skin})}^{\text{prior}}}{\underbrace{P(x)}_{\text{posterior}}}$$

$$P(\text{skin} | x) \propto P(x | \text{skin})P(\text{skin})$$

*Where does the prior come from?*

*Why use a prior?*

---

---

---

---

---

---

---

---

### Example: classifying skin pixels

Now for every pixel in a new image, we can estimate probability that it is generated by skin.

Brighter pixels →  
higher probability  
of being skin

Classify pixels based on these probabilities

- if  $p(\text{skin} | \mathbf{x}) > \theta$ , classify as skin
- if  $p(\text{skin} | \mathbf{x}) < \theta$ , classify as not skin

---

---

---

---

---

---

---

---

### Supervised classification

- Want to minimize the expected misclassification
- Two general strategies
  - Use the training data to build representative probability model; separately model class-conditional densities and priors (*generative*)
  - Directly construct a good decision boundary, model the posterior (*discriminative*)

---

---

---

---

---

---

---

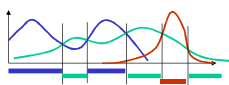

---

### General classification

This same procedure applies in more general circumstances

- More than two classes
- More than one dimension

Example: face detection

- Here, X is an image region
  - dimension = # pixels
  - each face can be thought of as a point in a high dimensional space

H. Schneiderman, T. Kanade. "A Statistical Method for 3D Object Detection Applied to Faces and Cars". IEEE Conference on Computer Vision and Pattern Recognition (CVPR 2000) <http://www2.eecs.berkeley.edu/~cs361/teach/cvpr00/p07.pdf>

### Today

- Supervised classification
- **Window-based generic object detection**
  - basic pipeline
  - boosting classifiers
  - face detection as case study

---

---

---

---

---

---

---

---

---

---

### Generic category recognition: basic framework

- Build/train object model
  - Choose a representation
  - Learn or fit parameters of model / classifier
- Generate candidates in new image
- Score the candidates

---

---

---

---

---

---

---

---

---

---

**Window-based models**  
**Building an object model**

Given the representation, train a binary classifier

---

### Boosting illustration

Weights Increased

---

---

---

---

---

---

---

---

---

---

---

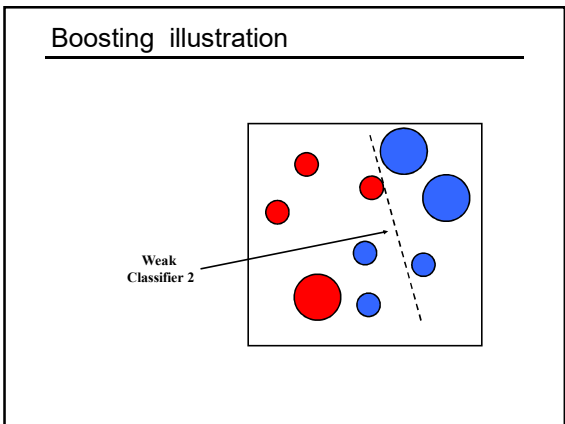

---

---

---

---

---

---

---

---

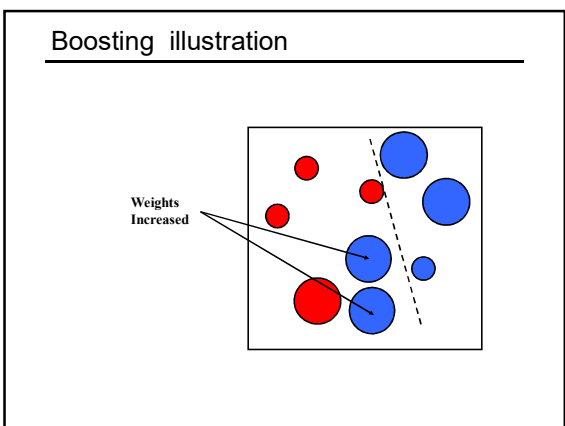

---

---

---

---

---

---

---

---

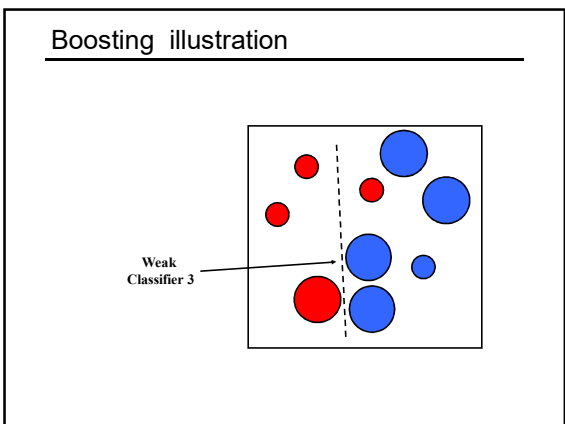

---

---

---

---

---

### Boosting illustration

Final classifier is a combination of weak classifiers

---

---

---

---

---

---

---

---

### Boosting: training

- Initially, weight each training example equally
- In each boosting round:
  - Find the weak learner that achieves the lowest *weighted* training error
  - Raise weights of training examples misclassified by current weak learner
- Compute final classifier as linear combination of all weak learners (weight of each learner is directly proportional to its accuracy)
- Exact formulas for re-weighting and combining weak learners depend on the particular boosting scheme (e.g., AdaBoost)

## Viola-Jones face detector

ACCEPTED CONFERENCE ON COMPUTER VISION AND PATTERN RECOGNITION 2001

### Rapid Object Detection using a Boosted Cascade of Simple Features

<p style="font-size: x-small;">Paul Viola viola@merl.com Mitsubishi Electric Research Labs 201 Broadway, 8th FL Cambridge, MA 02139</p>	<p style="font-size: x-small;">Michael Jones mjones@crl.dec.com Compaq CRL One Cambridge Center Cambridge, MA 02142</p>
---	---

**Abstract**

This paper describes a machine learning approach for vi-  
 detected at 15 frames per second on a conventional 700 MHz  
 Intel Pentium III. In other face detectors systems, auxiliary  
 information, such as image differences in video sequences,

---

---

---

---

---

---

---

---

## Viola-Jones face detector

### Main idea:

- Represent local texture with efficiently computable "rectangular" features within window of interest
- Select discriminative features to be weak classifiers
- Use boosted combination of them as final classifier
- Form a cascade of such classifiers, rejecting clear negatives quickly

---

---

---

---

---

---

---

---

## Viola-Jones detector: features

**"Rectangular" filters**  
Feature output is difference between adjacent regions

Efficiently computable with integral image: any sum can be computed in constant time.

Slide: Kristen Grauman

---

---

---

---

---

---

---

---

## Computing the integral image

Lana Lazebnik

---

---

---

---

---

---

---

---

### Computing the integral image

Cumulative row sum:  $s(x, y) = s(x-1, y) + i(x, y)$   
 Integral image:  $ii(x, y) = ii(x, y-1) + s(x, y)$

Lana Lazebnik

---

---

---

---

---

---

---

---

### Computing sum within a rectangle

- Let A,B,C,D be the values of the integral image at the corners of a rectangle
- Then the sum of original image values within the rectangle can be computed as:  
 $sum = A - B - C + D$
- Only 3 additions are required for any size of rectangle!

Lana Lazebnik

---

---

---

---

---

---

---

---

### Viola-Jones detector: features

**"Rectangular" filters**  
 Feature output is difference between adjacent regions

Efficiently computable with integral image: any sum can be computed in constant time  
 Avoid scaling images → scale features directly for same cost

Lana Lazebnik

---

---

---

---

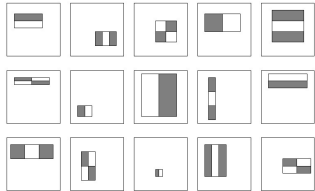

---

---

---

---

### Viola-Jones detector: features

Considering all possible filter parameters: position, scale, and type:  
180,000+ possible features associated with each 24 x 24 window

*Which subset of these features should we use to determine if a window has a face?*

Use AdaBoost both to select the informative features and to form the classifier

---

---

---

---

---

---

---

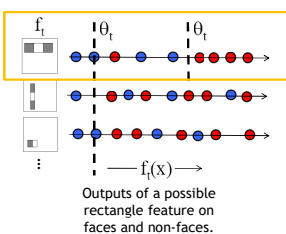

---

---

---

### Viola-Jones detector: AdaBoost

- Want to select the single rectangle feature and threshold that best separates **positive** (faces) and **negative** (non-faces) training examples, in terms of *weighted error*.

Outputs of a possible rectangle feature on faces and non-faces.

Resulting weak classifier:

$$h_t(x) = \begin{cases} +1 & \text{if } f_t(x) > \theta_t \\ -1 & \text{otherwise} \end{cases}$$

For next round, reweight the examples according to errors, choose another filter/threshold combo.

Slide: Kristen Grauman

---

---

---

---

---

---

---

---

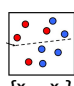

---

---

- Given example images  $(x_1, y_1), \dots, (x_n, y_n)$  where  $y_i = 0, 1$  for negative and positive examples respectively.
- Initialize weights  $w_{i,j} = \frac{1}{2m}, \frac{1}{2p}$  for  $y_i = 0, 1$  respectively, where  $m$  and  $p$  are the number of negatives and positives respectively.
- For  $t = 1, \dots, T$ :
  - Normalize the weights,
 
$$w_{i,j} \leftarrow \frac{w_{i,j}}{\sum_{j=1}^n w_{i,j}}$$
 so that  $w_i$  is a probability distribution.
  - For each feature,  $j$ , train a classifier  $h_j$  which is restricted to using a single feature. The error is evaluated with respect to  $w_i, e_j = \sum_i w_i |h_j(x_i) - y_i|$ .
  - Choose the classifier,  $h_t$ , with the lowest error  $e_t$ .
  - Update the weights:
 
$$w_{i,j+1} = w_{i,j} \beta_t^{1 - e_i}$$
 where  $e_i = 0$  if example  $x_i$  is classified correctly,  $e_i = 1$  otherwise, and  $\beta_t = \frac{e_t}{1 - e_t}$ .
- The final strong classifier is:
 
$$h(x) = \begin{cases} 1 & \sum_{t=1}^T \alpha_t h_t(x) \geq \frac{1}{2} \sum_{t=1}^T \alpha_t \\ 0 & \text{otherwise} \end{cases}$$
 where  $\alpha_t = \log \frac{1}{\beta_t}$

#### AdaBoost Algorithm

Start with uniform weights on training examples

$\{x_1, \dots, x_n\}$

For T rounds

- Evaluate **weighted error** for each feature, pick best.
- Re-weight the examples:
  - Incorrectly classified -> more weight
  - Correctly classified -> less weight

Final classifier is combination of the weak ones, weighted according to error they had.

---

---

---

---

---

---

Visual Object Recognition Tutorial

### Viola-Jones Face Detector: Results

First two features selected

---

---

---

---

---

---

---

---

- Even if the filters are fast to compute, each new image has a lot of possible windows to search.
- How to make the detection more efficient?

---

---

---

---

---

---

---

---

### Cascading classifiers for detection

```

    graph TD
      A[All sub-windows, multiple scales] --> B((Stage 1 classifier))
      B -- Face --> C((Stage 2 classifier))
      B -- Non-face --> D[Rejected sub-windows]
      C -- Face --> E((Stage 3 classifier))
      C -- Non-face --> D
      E -- Face --> F[Detection at a sub-window]
      E -- Non-face --> D
      style D fill:none,stroke:none
  
```

More features, lower false positive rates

- Form a *cascade* with low false negative rates early on
- Apply less accurate but faster classifiers first to immediately discard windows that clearly appear to be negative

Slide: Kristen Grauman

---

---

---

---

---

---

---

---

### Training the cascade

- Set target detection and false positive rates for each stage
- Keep adding features to the current stage until its target rates have been met
  - Need to lower AdaBoost threshold to maximize detection (as opposed to minimizing total classification error)
  - Test on a *validation set*
- If the overall false positive rate is not low enough, then add another stage
- Use false positives from current stage as the negative training examples for the next stage

---

---

---

---

---

---

---

---

### Viola-Jones detector: summary

Train with 5K positives, 350M negatives  
 Real-time detector using 38 layer cascade  
 6061 features in all layers

[Implementation available in OpenCV]  
 Slide: Kristen Grauman

---

---

---

---

---

---

---

---

### Viola-Jones detector: summary

- A seminal approach to real-time object detection
  - 15,000 citations and counting
- Training is slow, but detection is very fast
- Key ideas
  - *Integral images* for fast feature evaluation
  - *Boosting* for feature selection
  - *Attentional cascade* of classifiers for fast rejection of non-face windows

### Boosting: pros and cons

- Advantages of boosting
  - Integrates classification with feature selection
  - Complexity of training is linear in the number of training examples
  - Flexibility in the choice of weak learners, boosting scheme
  - Testing is fast
  - Easy to implement
- Disadvantages
  - Needs many training examples
  - Other discriminative models may outperform in practice (SVMs, CNNs,...)
    - especially for many-class problems

### Window-based detection: strengths

- Sliding window detection and global appearance descriptors:
  - Simple detection protocol to implement
  - Good feature choices critical
  - Past successes for certain classes

Visual Object Recognition Tutorial

### Window-based detection: Limitations

- High computational complexity
  - For example: 250,000 locations x 30 orientations x 4 scales = 30,000,000 evaluations!
  - If training binary detectors independently, means cost increases linearly with number of classes
- With so many windows, false positive rate better be low

Visual Object Recognition Tutorial

### Limitations (continued)

- Not all objects are “box” shaped

Visual Object Recognition Tutorial

### Limitations (continued)

- Non-rigid, deformable objects not captured well with representations assuming a fixed 2d structure; or must assume fixed viewpoint
- Objects with less-regular textures not captured well with holistic appearance-based descriptions

Visual Object Recognition Tutorial

### Limitations (continued)

- If considering windows in isolation, context is lost

Visual Object Recognition Tutorial

### Limitations (continued)

- In practice, often entails large, cropped training set (expensive)
- Requiring good match to a global appearance description can lead to sensitivity to partial occlusions

## Summary

- Basic pipeline for window-based detection
  - Model/representation/classifier choice
  - Sliding window and classifier scoring
- Boosting classifiers: general idea
- Viola-Jones face detector
  - Exemplar of basic paradigm
  - Plus key ideas: rectangular features, Adaboost for feature selection, cascade
- Pros and cons of window-based detection
